# Statistical Learning

#### Canonical scenario

- 1 an outcome measurement (or response, output)
  - either quantitative (expression level, tumor size, survival time, etc.)
  - or categorical (presence/absence of a gene or of a disease, etc.)
- 2 a set of features (or predictors, inputs)
  - clinical measurements (expression level, tumor size)
  - age, smoking or not, height, SNPs, etc.

#### Learning problem

Given a training set of data (observed inputs and outputs), we aim to

- 1 suggest a model,
- ② learn this model on the training set,
- 3 test this model on new outcomes/features.
- → A "good" model should accurately predict new outcomes.

## **Notations**

#### Let

- Y be the output random variable,
- $X = (X_1, \dots, X_p)$  be the input random variables, where  $X_j$  is the j predictor.

#### The data

Given a sample  $\{(y_i, x_i), i = 1, \dots, n\}$  of i.id. realizations of (Y, X), denote

- $\mathcal{D} = \{i : (y_i, x_i) \in \text{ training set}\},$
- $\mathcal{T} = \{i : (y_i, x_i) \in \text{test set}\},$
- $\mathbf{y} = (y_i)_{i \in \mathcal{D}}$ , the *response* vector in  $\mathbb{R}^{|\mathcal{D}|}$ ,
- $\mathbf{x}_j = (x_{ij})_{i \in \mathcal{D}}^{\mathsf{T}}$ ) the vector of data for the jth predictor in  $\mathbb{R}^{|\mathcal{D}|}$ ,
- X the  $n \times p$  data (or design) matrix on the training set whose jth row is  $\mathbf{x}_j$ ,
- $\bullet \ (\mathbf{y}_{\mathcal{T}}, \mathbf{X}_{\mathcal{T}})$  are the test data.

# Regression models

We seek a function f that predicts Y through X.

## Proposition

The model  $f(X) = \mathbb{E}[Y|X]$  minimizes the squared error loss, that is,

$$f(X) = \mathop{\arg\min}_{\varphi} \operatorname{err}(\varphi(X)), \quad \textit{with} \ \operatorname{err}(\varphi(X)) = \mathbb{E}[(Y - \varphi(X))^2].$$

 $\leadsto$  The best prediction of Y at any point X=x is the conditional mean, when best is measured by average squared error.

This leads to the regression model

$$Y = f(X) + \varepsilon,$$

#### where

- $\varepsilon$  is an additive error with  $\mathbb{E}[\varepsilon] = \mathbf{0}$ ,  $\mathbb{V}[\varepsilon] = \sigma^2$ ,
- $f(x) = \mathbb{E}[Y|X = x]$  is the *regression* function.

# Learning strategy

#### Problem

 $\mathbb{P}(Y|X)$  and  $\mathbb{P}(X)$  are unknown thus  $\mathbb{E}(Y|X), \operatorname{err}(f(X))$  unreachable: one should estimate this.

## Strategy

- **1** Fix a family  $\mathcal{F}$  of models For the linear model,  $\mathcal{F} = \{X^T \beta, \beta \in \mathbb{R}^p\}$ .
- ② Fit a model  $\hat{f} \in \mathcal{F}$  on the training set  $\mathcal{D}$  With the least square, compute  $\hat{\beta}^{\text{ols}}$  and  $\hat{f} = \hat{Y} = \hat{X} \hat{\beta}^{\text{ols}}$
- $\ensuremath{\mathfrak{S}}$  Estimate the prediction error with the test set  $\ensuremath{\mathcal{T}}.$

For instance, 
$$\hat{\text{err}}(\mathbf{X}_{\mathcal{T}}\hat{\boldsymbol{\beta}}^{\text{ols}}) = \frac{1}{n} \left\| \mathbf{y}_{\mathcal{T}} - \mathbf{X}_{\mathcal{T}}\hat{\boldsymbol{\beta}}_{\mathcal{D}}^{\text{ols}} \right\|^2$$
.

# Learning strategy

#### Problem

 $\mathbb{P}(Y|X)$  and  $\mathbb{P}(X)$  are unknown thus  $\mathbb{E}(Y|X), \operatorname{err}(f(X))$  unreachable: one should estimate this.

## Strategy

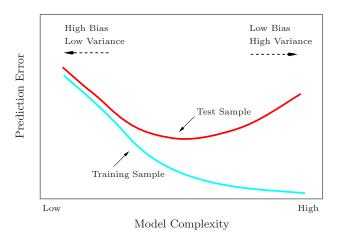

- **1** Fix a family  $\mathcal{F}$  of models For the linear model,  $\mathcal{F} = \{X^T \boldsymbol{\beta}, \boldsymbol{\beta} \in \mathbb{R}^p\}$ .
- ② Fit a model  $\hat{f} \in \mathcal{F}$  on the training set  $\mathcal{D}$  With the least square, compute  $\hat{\boldsymbol{\beta}}^{\mathrm{ols}}$  and  $\hat{f} = \hat{Y} = \mathbf{X}\hat{\boldsymbol{\beta}}^{\mathrm{ols}}$
- $\ensuremath{\mathfrak{S}}$  Estimate the prediction error with the test set  $\mathcal{T}$ .

For instance, 
$$\hat{\text{err}}(\mathbf{X}_{\mathcal{T}}\hat{\boldsymbol{\beta}}^{\text{ols}}) = \frac{1}{n} \left\| \mathbf{y}_{\mathcal{T}} - \mathbf{X}_{\mathcal{T}}\hat{\boldsymbol{\beta}}_{\mathcal{D}}^{\text{ols}} \right\|^{2}$$
.

# Bias/variance tradeoff

At an input point X = x,

$$\operatorname{err}(\hat{f}(x)) = \underbrace{\sigma^2}_{\substack{\text{incompressible} \\ \text{error}}} + \underbrace{\operatorname{bias}^2(\hat{f}(x)) + \mathbb{V}(\hat{f}(x))}_{\substack{\text{MSE}(\hat{f}(x))}}.$$

# Linear regression

#### Prediction error

For a fixed X, one has

$$\hat{\operatorname{err}}(\mathbf{X}\hat{\boldsymbol{\beta}}^{\operatorname{ols}}) = \sigma^2 \frac{(p+1)}{n} + \sigma^2.$$

#### Gauss-Markov Theorem

 $\hat{Y}=X^{\rm T}\hat{\boldsymbol{\beta}}^{\rm ols}$  is the BLUE: the best model (i.e. with the smallest variance) among unbiased estimators of  $\boldsymbol{\beta}$ .

 $\leadsto$  Are they some cases where we should trade some bias for smaller variance ?

## Comments

Why do some coefficients in  $\beta$  are not well estimated/ have large variance? (pgg45, gleason)

#### Statistical issue

Correlated variables are not well estimated,

→ they carry the same information regarding the response.

#### Numerical issue

Correlated variables leads to bad conditioning of  $X^TX$ ,

 $\leadsto$  OLS cannot be computed when they are redundant variables in  ${\bf X}$  or when n < p.

→ interpretation becomes rather difficult

## Solutions

#### Variable selection

If the underlying model is assumed to have only few predictors truly related to the outcome, we may want to select those with the highest effect. We are looking for both

- · better interpretability.
- better predictive performances.

#### Regularization

If all the predictors have similar or close effects on the response, selection (and thus interpretability) is out of reach.

We may regularize the problem by constraining the parameters  $\beta$  to live in an appropriate set that will make the  $\mathbf{X}^T\mathbf{X}$  invertible.

- Motivations
- 2 Variable Selection

Criteria for model comparison Algorithms for variable subset selection Illustration: prostate cancer

3 Regularisation

## Variable Selection

#### Problematic

With many regressor,

- we integrate more and more information in the model;
- we have more and more parameters to estimate and  $\mathbb{V}(\hat{Y}_i)$   $\nearrow$ .

#### Idea

Look for a (small) set  ${\mathcal S}$  with k variables among p such that

$$Y \approx X_{\mathcal{S}}^T \hat{\boldsymbol{\beta}}_{\mathcal{S}}.$$

#### Ingredients

To find this tradeoff, we need

- a criterion to evaluate the performance;
- $oldsymbol{2}$  an algorithm to determine the subset of k variables optimising the criterion.

- Motivations
- 2 Variable Selection Criteria for model comparison

Algorithms for variable subset selection Illustration: prostate cancer

3 Regularisation

# Estimation of the prediction error by cross-validation

For the regression: PRESS (predicted residual sum of squares)

## Principe

- lacktriangle Split the data into K subsets,
- Successively use each subset as the test set,
- $oldsymbol{3}$  Compute the test error for the K subsets,
- f 4 Average the K error to get the final estiamte.

#### **Formalism**

Let  $\kappa:\{1,\ldots,n\}\to\{1,\ldots,K\}$  be an indexing function that indicates the partition to which observation i is allocated by randomization. Denote by  $\hat{f}^{-\kappa(i)}$  the fitted model, computed with the kth part of the data removed. Then

$$CV(\hat{\boldsymbol{\beta}}) = \frac{1}{n} \sum_{i=1}^{n} (y_i - x_i^T \hat{\boldsymbol{\beta}}^{-\kappa(i)})^2$$

provides an estimate of the prediction error.

## Penalized Criterion

#### Principle

#### Idea

Rather than estimating the prediciton error with the test error, we estimate how much the training error under estimate the true prediction error.

#### General form

Based on the available model fit, compute

$$\hat{\text{err}} = \text{err}_{\mathcal{D}} + \text{"optimism"}.$$

#### Remarks

"penalize" to much complex models

## Penalized Criteria

The most Popular in linear regression

Let k be the size of the current model (i.e. the current number of predictors).

Criterion for the Linear regression model  $\sigma$  known

We choose the model with size k minimizing one of the following

• Akaïke Information Criteria equivalent to  $C_p$  when  $\sigma$  is known

$$AIC = -2loglik + 2k = \frac{n}{\sigma^2}err_{\mathcal{D}} + 2k.$$

• Bayesian Information Criterion

BIC = 
$$-2 \log \operatorname{lik} + k \log(n) = \frac{n}{\sigma^2} \operatorname{err}_{\mathcal{D}} + k \log(n)$$
.

## Penalized Criteria

The most Popular in linear regression

Let k be the size of the current model (i.e. the current number of predictors).

Criterion for the Linear regression model  $\sigma$  unknown

We choose the model with size k minimizing one of the following

• Akaïke Information Criteria  $\sigma^2$  estimated by  $\mathrm{err}_{\mathcal{D}}/n$ 

$$AIC = -2loglik + 2k = n \log(err_{\mathcal{D}}) + 2k.$$

• Bayesian Information Criterion  $\sigma^2$  estimated by  $\mathrm{err}_{\mathcal{D}}/n$ 

$$BIC = -2\log lik + k \log(n) = n \log(err_{\mathcal{D}}) + k \log(n).$$

# Exhaustive search (best-subset)

## Algorithm

For  $k=0,\ldots,p$ , find the subset with k variables with the smallest SCR among  $2^k$  models.

#### **Properties**

- Generalize to any criterion  $(R^2, AIC, BIC...)$
- Efficient algorithm with pruning ("Leaps and Bound")
- impossible as soon as p > 30.

# (Forward regression)

## Algorithm

- 1. Begin with  $S = \emptyset$
- 2. at step k find the variable which, added to S, gives the best model
- 2'. At step k find the best model by either adding or removing one variable
  - 3 etc. until p variables enter the model

## **Properties**

- Best model is understood asadjusted  $R^2$ , AIC, BIC...
- ullet useful when p is large
- large bias, but variance/complexity controlled.
- "greedy" algorithm

# Forward-stepwise

## Algorithm

- 1. Begin with  $S = \emptyset$
- 2. at step k find the variable which, added to S, gives the best mode
- 2'. At step k find the best model by either adding or removing one variable.
  - 3 etc. until p variables enter the model

### **Properties**

## Comments

### Interpretability

- If the true S only contains a few variables linked to the response, → variable selection algorithms can retrieve relevent predictors.
- ② If the true S contains many correlated predictors → the selected variables will be hardly interpretable.

### Stability issue

With strong correlation or when n < p, small changes in the data can induce large discrepencies between the sets of selected variables.

# Several goals

## Control the parameter $\hat{m{\beta}}$ to

- Regularize the problem
  - For numerical purpose, (conditioning of  $X^TX$ ),
  - For stability purpose, (correlation between  $(X_1, \ldots, X_p)$ ).
- Enhance the prediction
  - By trading a little bias vs variance
  - · By controlling irrelevant variables
- 3 Looking towards interpretability
  - By controlling model complexity,
  - By embedding the variable selection (Lasso).

#### Constrained Optimization

We basically want to solve a problem of the form

$$\underset{\beta_1,\beta_2}{\text{maximize}} L(\beta_1,\beta_2;\mathbf{X})$$

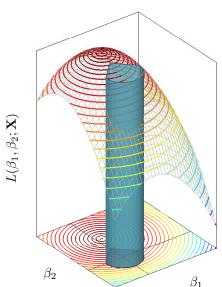

where L is typically a concave likelihood function.

This is strictly equivalent to solve

$$\underset{\beta_1,\beta_2}{\operatorname{minimize}} L'(\beta_1,\beta_2;\mathbf{X})$$

where  $L^\prime = -L$  is convex ! For instance the squared error loss in the OLS.

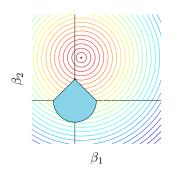

### Constrained Optimization

$$\begin{cases} \underset{\beta_1,\beta_2}{\text{maximize}} & L(\beta_1,\beta_2;\mathbf{X}) \\ \text{s.t.} & \Omega(\beta_1,\beta_2) \leq c \end{cases},$$

where  $\Omega$  defines a domain that *constrains*  $\beta$ .

Constrained Optimization

$$\begin{cases} \underset{\beta_1,\beta_2}{\text{maximize}} & L(\beta_1,\beta_2;\mathbf{X}) \\ \text{s.t.} & \Omega(\beta_1,\beta_2) \leq c \end{cases},$$

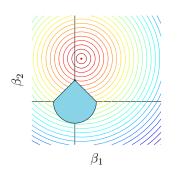

where  $\Omega$  defines a domain that constrains  $\beta$ .

with J the convex objective defined by

$$J(\boldsymbol{\beta}) = -L(\beta_1, \beta_2; \mathbf{X}) + \lambda \Omega(\beta_1, \beta_2)$$

Constrained Optimization

$$\begin{cases} & \underset{\beta_1, \beta_2}{\text{maximize}} & L(\beta_1, \beta_2; \mathbf{X}) \\ & \text{s.t.} & \Omega(\beta_1, \beta_2) \leq c \end{cases} ,$$

where  $\Omega$  defines a domain that *constrains*  $\beta$ .

$$\underset{\beta_1,\beta_2}{\text{minimize}} J(\boldsymbol{\beta}),$$

with J the convex objective defined by

$$J(\boldsymbol{\beta}) = -L(\beta_1, \beta_2; \mathbf{X}) + \lambda \Omega(\beta_1, \beta_2)$$

How shall we define  $\Omega$  ?

## Definition

#### Fact

If the  $\beta_j$  are unconstrained, they can have very high magnitude and thus large variances.

#### Idea

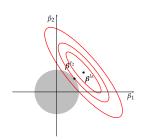

To control the variance, we should control the size of the coefficients in  $\beta$ . This could induce a large decrease of the prediction error.

### Ridge as a regularization problem

The ridge estimate of  $\beta$  is the solution to

$$\hat{\boldsymbol{\beta}}^{\mathsf{ridge}} = \mathop{\arg\min}_{\boldsymbol{\beta} \in \mathbb{R}^{p+1}} \mathrm{RSS}(\boldsymbol{\beta}), \quad \mathsf{s.t.} \ \sum_{j=1}^p \beta_j^2 \leq s,$$

where  $\boldsymbol{s}$  is a shrinkage factor.

# A 2-dimensional toy example

Consider that the true relationship is  $Y=X_1\beta_1+X_2\beta_2+\varepsilon$  If  $X_1$  and  $X_2$  are strongly correlated, then  $X_1\approx X_2$  and for any  $\gamma\geq 0$ 

$$Y = X_1(\beta_1 + \gamma) + X_2(\beta_2 - \gamma) + \gamma(X_1 - X_2) + \varepsilon$$
  
 
$$\approx X_1(\beta_1 + \gamma) + X_2(\beta_2 - \gamma) + \varepsilon.$$

A large panel of fit with estimated  ${\cal B}$  varying according to  $\gamma$  will produce the same prediction error.

For small s (or large  $\lambda$  in the Lagrangian form), the ridge controls

$$(\beta_1 + \gamma)^2 + (\beta_2 - \gamma)^2$$

which is minimal for  $\gamma = (\beta_2 - \beta_1)/2$ , and in this case  $\beta_j = (\beta_1 + \beta_2)/2$ .

# A 2-dimensional toy example

Consider that the true relationship is  $Y=X_1\beta_1+X_2\beta_2+\varepsilon$  If  $X_1$  and  $X_2$  are strongly correlated, then  $X_1\approx X_2$  and for any  $\gamma\geq 0$ 

$$Y = X_1(\beta_1 + \gamma) + X_2(\beta_2 - \gamma) + \gamma(X_1 - X_2) + \varepsilon$$
  
 
$$\approx X_1(\beta_1 + \gamma) + X_2(\beta_2 - \gamma) + \varepsilon.$$

A large panel of fit with estimated  $m{\beta}$  varying according to  $\gamma$  will produce the same prediction error.

For small s (or large  $\lambda$  in the Lagrangian form), the ridge controls

$$(\beta_1 + \gamma)^2 + (\beta_2 - \gamma)^2$$

which is minimal for  $\gamma = (\beta_2 - \beta_1)/2$ , and in this case  $\beta_j = (\beta_1 + \beta_2)/2$ .

# A 2-dimensional toy example (in R) I

### Generate two correlated predictors

```
suppressMessages(library(quadrupen)) # use github version
x1 <- rnorm(5)
x2 <- x1 + rnorm(5,0, 0.5)
cor(x1,x2)
## [1] 0.7316593</pre>
```

### Draw Y and plot the ridge regularisation path

```
library(glmnet)
y <- x1 + x2 +rnorm(5)
plot(quadrupen::ridge(cbind(x1,x2),y))

## Error: 'ridge' is not an exported object from 'namespace:quadrupen'</pre>
```

# Ridge as penalized regression

Dont penalize the intercept thus consider  $\boldsymbol{\beta}=(\beta_1,\ldots\beta_p)$  and set

- $\hat{\beta}_0 = \bar{\mathbf{y}} \bar{x}\hat{\boldsymbol{\beta}}$
- center y and  $\mathbf{x}_i$ ,  $j = 1, \dots, p$ .

Standardize the  $\mathbf{x}_j$  for the fit and send back  $\hat{\boldsymbol{\beta}}^{\mathrm{ridge}}$  to the orginal scale.

### Convex Langrangian form

$$\begin{split} \hat{\boldsymbol{\beta}}^{\mathsf{ridge}} &= \mathop{\mathrm{arg~min}}_{\boldsymbol{\beta} \in \mathbb{R}^p} \frac{1}{2} \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|^2 + \lambda \|\boldsymbol{\beta}\|^2 \\ &= (\mathbf{X}^\intercal \mathbf{X} + \lambda \mathbf{I}_p)^{-1} \mathbf{X}^\intercal \mathbf{y} = \mathbf{H}_\lambda \mathbf{y}. \end{split}$$

### Strong convexity

Oppositely to the least squares, a non-singular solution always exists when  $\lambda > 0$  whatever the conditioning of  $\mathbf{X}^{\mathsf{T}}\mathbf{X}$  (original proposal).

# Ridge fit for the prostate cancer data

### Compute the ridge path

```
ridge_path <- quadrupen::ridge(x_train, y_train)
## Error: 'ridge' is not an exported object from 'namespace:quadrupen'
```

### Compute the prediction error on the test set for all $\lambda$

```
err <- colMeans((y_test - predict(ridge_path, as.matrix(x_test)))^2)
## Error in predict(ridge_path, as.matrix(x_test)): object 'ridge_path' not found
```

### Then, $\lambda^*$ that minimizes this error

```
ridge_path@lambda2[which.min(err)]
## Error in eval(expr. envir. enclos): object 'ridge_path' not found
```

### The prediction error is smaller than with the OLS

```
err_ridge <- err[which.min(err)]</pre>
## Error in eval(expr, envir, enclos): object 'err' not found
print(err_ridge)
## Error in print(err_ridge): object 'err_ridge' not found
print(err ols)
```

## Error in plot(ridge\_path): object 'ridge\_path' not found

Motivations et principle

Ridge regression

The ridge estimator

Model complexity and Tuning parameter

Lasso Regression

Definition of the LASSO estimator

# Classical options

#### Cross-validation

We compute  $CV(\lambda)$ , the CV error along the  $\lambda$  path

- $\bullet$  if K=n, this is the LOOCV,
- $\mathbf{Q}$  if K=2, this is the hold out estimation,
- $\odot$  in a high dimensional setup, we must choose K "carefully",

We choose  $\lambda$  minimising the CV

#### Penalized criteria

We choose  $\lambda$  minimizing a criterion with the form

$$\operatorname{crit}(\lambda) = \operatorname{err}_{\mathcal{D}}(\lambda) + \operatorname{pen}(\operatorname{df}_{\lambda})$$

→ What sens give to the degrees of freedom for ridge regression?

# Effective degrees of freedom

- Degrees of freedom of a model describes its complexity level.
- For the least squares, df = p (plus 1 for the intercept).
- Need a definition adapted to shrinkage methods.

### Definition (Efron and others)

Consider a fitted vector  $\hat{\mathbf{y}}$  from an observation  $\mathbf{y}.$  We define its degrees of freedom as

$$df(\hat{\mathbf{y}}) = \frac{1}{\sigma^2} \sum_{i=1}^n cov(\hat{y}_i, y_i).$$

→ The harder the fit to the data, the higher the covariance.

# Effective degrees of freedom: the ridge case

### Proposition

Consider a linear fitting method that predicts  $\hat{\mathbf{y}}$  for entry  $\mathbf{y}$  through the smoother matrix  $\mathbf{H}$ :

$$\hat{\mathbf{y}} = \mathbf{H}\mathbf{y}$$
.

The effective degrees of freedom of the model  $\hat{\mathbf{y}}$  verifies

$$df(\hat{\mathbf{y}}) = Tr(\mathbf{H}).$$

### Ridge: effective degrees of freedom

For ridge regression, df is a decreassig function of  $\lambda$  which tends to 0 (or 1 when considering the intercept):

$$df(\hat{\mathbf{y}}_{\lambda}) = \sum_{i=1}^{p} \frac{d_i^2}{d_i^2 + \lambda}.$$

## Cross-Validation

### Cross-validation is easily parallelized and is fast on small data sets

```
system.time(loo <- quadrupen::crossval(x_train,y_train, penalty = "ridge", K = n))
## Error in match.arg(penalty): 'arg' should be one of "elastic.net", "bounded.reg"

system.time(CV10 <- quadrupen::crossval(x_train,y_train, penalty = "ridge", K = 10))
## Error in match.arg(penalty): 'arg' should be one of "elastic.net", "bounded.reg"</pre>
```

## Leave one out

```
## Error in plot(loo, main = "LOO CV error"): object 'loo' not found
```

## Ten fold

```
## Error in plot(CV10, main = "10-fold CV error"): object 'CV10' not found
```

## The Lasso

Least Absolute Shrinkage and Selection Operator

#### Fact

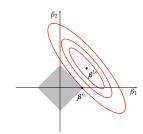

Ridge performs regularization...but we also would like to select the most significant variables.

#### Idea

Suggest an admissible set that induces sparsity (force several entries to exactly zero in  $\hat{\beta}$ ).

Lasso as a convex optimization problem

The Lasso estimate  $\hat{oldsymbol{eta}}^{\mathsf{lasso}}$  solves

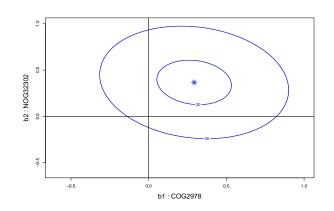

where s is a shrinkage factor.

# Some more insights: 2-dimensional example

$$\sum_{i=1}^n (y_i - x_i^1 \beta_1 - x_i^2 \beta_2)^2, \qquad \text{no constraints}$$

# Some more insights: 2-dimensional example

Thanks to Sylvie Huet

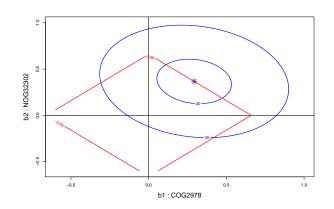

$$\sum_{i=1}^{n} (y_i - x_i^1 \beta_1 - x_i^2 \beta_2)^2, \quad \text{s.c. } |\beta_1| + |\beta_2| < 0.75$$

# Some more insights: 2-dimensional example

Thanks to Sylvie Huet

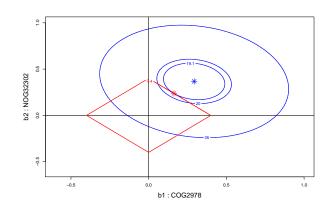

$$\sum_{i=1}^n (y_i - x_i^1 \beta_1 - x_i^2 \beta_2)^2, \quad \text{s.c. } |\beta_1| + |\beta_2| < 0.66$$

# Some more insights: 2-dimensional example

Thanks to Sylvie Huet

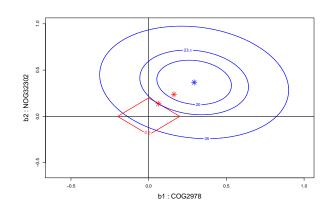

$$\sum_{i=1}^{n} (y_i - x_i^1 \beta_1 - x_i^2 \beta_2)^2, \quad \text{s.c. } |\beta_1| + |\beta_2| < 0.4$$

## Some more insights: 2-dimensional example

Thanks to Sylvie Huet

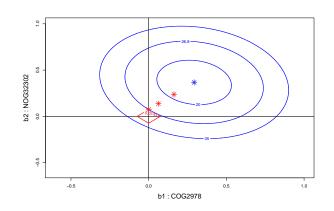

$$\sum_{i=1}^n (y_i - x_i^1 \beta_1 - x_i^2 \beta_2)^2, \qquad \text{s.c. } |\beta_1| + |\beta_2| < 0.2$$

# Some more insights: 2-dimensional example

Thanks to Sylvie Huet

$$\sum_{i=1}^n (y_i - x_i^1 \beta_1 - x_i^2 \beta_2)^2, \qquad \text{s.c. } |\beta_1| + |\beta_2| < 0.0743$$

## Lasso as penalized regression

#### Get rid of the intercept

We should not penalize the intercept term, thus

- $\hat{\beta}_0 = \bar{\mathbf{y}}$ ,
- center  $\mathbf{y}$  and  $\mathbf{x}_j$ ,  $j = 1, \dots, p$ ,
- scale the predictor before the fit,
- send  $\hat{oldsymbol{eta}}$  back to the original scale.

Solve the convex,  $\ell_1$ -penalized problem

$$\hat{\boldsymbol{\beta}}^{\mathsf{lasso}} = \operatorname*{arg\ min}_{\boldsymbol{\beta} \in \mathbb{R}^p} \frac{1}{2} \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|^2 + \lambda \|\boldsymbol{\beta}\|_1,$$

whose solution has no close form, but always exists and is unique as soon as  $X^TX$  has full rank.

→ Lasso performs regularization and variable selection but has no analytical solution.

# Lasso fit on the prostate cancer data I

#### Compute the LASSO path

```
library(glmnet)
lasso_path <- quadrupen::lasso(x_train,y_train)

## Error: 'lasso' is not an exported object from 'namespace:quadrupen'</pre>
```

### Compute the prediction error on the test set for all $\lambda$

```
err <- colMeans((y_test - predict(lasso_path, x_test))^2)
## Error in predict(lasso_path, x_test): object 'lasso_path' not found</pre>
```

#### Then, $\lambda^*$ that minimizes this error

```
lasso_path@lambda1[which.min(err)]
## Error in eval(expr, envir, enclos): object 'lasso_path' not found
```

# Lasso fit on the prostate cancer data II

#### The prediction error is smaller than with the OLS with only 5 coefficients

```
err[which.min(err)]
## Error in eval(expr, envir, enclos): object 'err' not found
lasso_path@coefficients[which.min(err), ]
## Error in eval(expr, envir, enclos): object 'lasso_path' not found
```

### Prediction error on the test set

```
